### Abstract

This document describes the Breadflower system — a specialized oven and dough preparation method designed for baking sprouted wheat bread without yeast. Inspired by alternative energy theories and holistic food science, the Breadflower oven leverages stainless steel materials and insulation layers to support an unorthodox fermentation and baking process. The system is intended to preserve subtle energetic qualities of sprouted grains.

Figure 1: Breadflower

# 1 Introduction

Sprouted wheat dough contains a wealth of nutrients and bioactive compounds that are typically lost in conventional breadmaking. In contrast, flour is made by grinding dead, dry wheat kernels into a sterile powder, devoid of the enzymatic life and vitality found in sprouted grains. Traditional baking methods further degrade these nutrients through excessive heat and improper fermentation. The Breadflower system addresses these issues by enabling a controlled, low-voltage baking environment that preserves the living essence of the sprouted dough while transforming it into nourishing, digestible bread.

## 2 Oven Construction

The oven is composed of concentric hemispherical shells of stainless steel. Between the shells is a composite insulator made of natural fibers such as wool and cotton. A 24VDC power source provides resistive heating to the outer shell, while the inner cavity holds a dough ball on a ceramic or steel pedestal.

### 3 Energy and Fermentation Hypothesis

Anecdotal evidence and legacy theories of "orgone energy" or vitalist fields suggest that sprouted grains may retain unique energetic signatures. The Breadflower is designed to preserve and potentially amplify such qualities through its materials and construction.

## 4 Breadflower: A System for Sprouted Wheat Dough Production and Baking

**Breadflower** is a system designed to produce nutrient-dense, yeast-free bread from live sprouted wheat. It is composed of two primary components:

- A hand-powered mill
- A 24VDC electric baking oven (referred to as *the womb*)

### 4.1 Sprouting Process

The process begins by placing a measured quantity of dry wheat berries into a container and covering them with water. The water is changed daily. By the second day, the wheat berries begin to show small sprout tails, indicating activation of the germination process.

### 4.2 Milling Assembly and Operation

The sprouted, moist wheat berries are loaded into a plastic funnel approximately 2 feet high and 3 inches wide. This funnel is mounted vertically on top of the hand mill. The mill features a Teflon core with a sloped entry port that gravity-feeds the berries into the grinding chamber.

The grinding chamber consists of:

- A stainless steel containment tube, 5 inches long and 1 inch in diameter
- An oval aperture (1 inch by 1.5 inches) that exposes the copper mill screw

The mill screw is a cylindrical component, 6 inches long and 1 inch in diameter, with a helical ridge along its surface. The ridge height tapers from 0.25 inches at the intake end to flat at the output end. As the screw is manually rotated, the wheat berries are drawn along the screw, compressed progressively, and pressed against the containment tube wall.

At the output end of the tube is a circumferential ring of 1mm expelling holes. These allow the compressed wheat material to exit under pressure.

### 4.3 Mixing and Dough Formation

Surrounding the expelling ring is a Teflon mixing chamber, into which the expressed material accumulates. Continued milling forces additional material into this chamber, forming a dense mass. A 1mm by 25mm slit at the chamber base allows the dough to extrude in ribbon form.

As ribbons accumulate on the wooden base, the user periodically gathers and kneads them into a single mass. The result is a softball-sized ball of integrated dough, dense and moist.

## 4.4 Baking in the Womb Oven

The dough ball is placed onto a thin, circular stainless steel reflector plate (8 inches in diameter), which forms a thermal seal with the *womb* — a hemispherical orgone-accumulating oven.

The womb is constructed of double-layered stainless steel with insulating cotton or wool batting between layers. A 24VDC heating coil is embedded along the lower interior circumference and secured with brackets.

The womb is placed over the dough and energized. During the 2-hour baking process, the dough expands to approximately 8 inches in diameter. This rise occurs without yeast, catalyzed by the thermal and energetic properties of the oven.

A handle at the top center contains a temperature probe port, allowing insertion of a standard food thermometer. When the bread reaches an internal temperature of 168°F, the oven is disconnected and removed. A food-safe plastic spatula is used to lift the bread from the heating plate.

## 4.5 Cleaning and Maintenance

After use, the mill screw and handle are disassembled. The screw is soaked in water to loosen any remaining dough and facilitate cleaning.

## 4.6 Final Product Characteristics

The resulting bread is dense and meat-like in texture, requiring a serrated knife for slicing. It is best served in 1-inch slices. The flavor is satisfying and nutritionally complete — often eliminating cravings for meat or other food groups. Common enhancements include olive oil and salt.

## 4.7 Variations and Applications

**Breakfast Variation:** Cinnamon sticks can be added to the soaking container. These soften and can be milled with the wheat, producing a cinnamon-infused dough ideal for buttered toast.

**Storage:** Bread can be stored in a cloth bag. By morning, it becomes dry and firm, ideal for slicing and toasting.

**Pasta Alternative:** Instead of collecting ribbons into a dough ball, the user may lay them flat on a sheet pan and dry them in sunlight. Once dried, the ribbons can be used like traditional pasta — for instance, layered with sauce and cheese to make lasagna.

## 5 Conclusion and Future Work

Breadflower proposes a new approach to baking sprouted grains that respects their living nature. Future work includes sensor integration, automation, and investigation of the energetic field hypothesis using modern techniques.
